# 1.1 Variable Description

In total, we have 21 variables related to demographic, services, and accountant data. One is the ID, three are numerical variables, and 17 are categorical variables. We will conduct a descriptive analysis and a data quality report for each variable, considering aspects such as the number of missing values, errors, and the distribution or balance of the variable...

#### customerID

We won't need this variable for the analysis nor the modelling.

#### 1.1.1 Demographic data

#### gender

Is a binary variable (female/male). It doesn't contain NA values.

```
## [1] 0
##
## Female Male
## 3488 3555
```

#### SeniorCitizen

It is a binary variable. Levels: 1(=yes)/0(=no). It doesn't contain NA values.

```
## [1] 0
##
## 0 1
## 5901 1142
```

#### Partner

It is a binary variable. Levels: Yes/No. It doesn't contain NA values.

```
## [1] 0
##
## No Yes
## 3641 3402
```

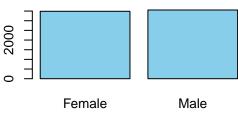

#### **Dependents**

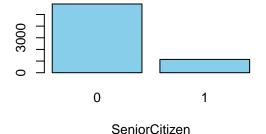

It is a binary variable. Levels: Yes/No. It doesn't contain NA values.

```
## [1] 0
##
## No Yes
## 4933 2110
```

## Distribution of gender

# **Distribution of SeniorCitizen**

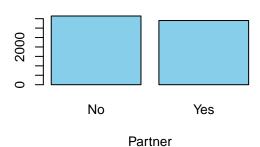

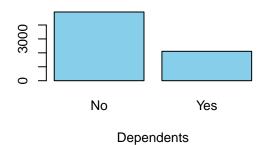

# Distribution of Partner

Gender

# **Distribution of Dependents**

#### 1.1.2 Services of the costumer data

Services that each customer has signed up for:

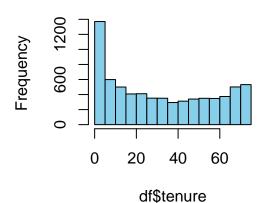

#### tenure

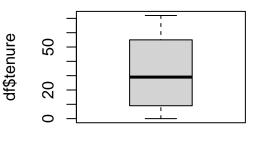

It is a numerical variable that indicates the duration, in months, that the customer has stayed with the company. We shall explore the statistics of the variable and look for the *outliers* 

## Min. 1st Qu. Median Mean 3rd Qu. Max. ## 0.00 9.00 29.00 32.37 55.00 72.00

# **Histogram**

# **Outlier analysis**

par(mfrow = c(1, 1))
sm\_t <- summary(df\$tenure)
iqr\_t <- sm\_t["3rd Qu."] - sm\_t["1st Qu."]</pre>

```
# Mild Outliers
mild_ub_t <- sm_t["3rd Qu."] + 1.5 * iqr_t
mild_lb_t <- sm_t["1st Qu."] - 1.5 * iqr_t
length(which(df$tenure > mild_ub_t | df$tenure < mild_lb_t))

## [1] 0
# number of mild outliers

# Severe Outliers
severe_ub_t <- sm_t["3rd Qu."] + 3 * iqr_t
severe_lb_t <- sm_t["1st Qu."] - 3 * iqr_t
length(which(df$tenure > severe_ub_t | df$tenure < severe_lb_t))

## [1] 0
# number of severe outliers</pre>
```

There are **no mild nor severe outliers** in Tenure.

#### **PhoneService**

It is a binary variable. Levels: Yes/No. It doesn't contain NA values.

```
## [1] 0
##
## No Yes
## 682 6361
```

#### MultipleLines

Categorical variable with 3 levels, No/No phone service/Yes. It doesn't contain NA values.

```
## [1] 0
##
## No No phone service Yes
## 3390 682 2971
```

Check for inconsistencies:

• It cannot happen that a costumer has not Phoneservice and Multiplelines.

```
## [1] customerID
                         gender
                                          SeniorCitizen
                                                           Partner
## [5] Dependents
                                                           MultipleLines

PaymentMethod

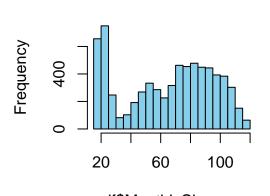

#### MonthlyCharges

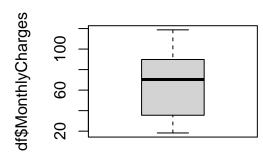

It is a numerical variable. It doesn't contain NA values.

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 18.25 35.50 70.35 64.76 89.85 118.75
```

# **Histogram**

# **Outlier analysis**

df\$MonthlyCharges

## [1] 0

Let's look for outliers.

```
sm <- summary(df$MonthlyCharges)
iqr <- sm["3rd Qu."] - sm["1st Qu."]
# Mild Outliers
mild_ub <- sm["3rd Qu."] + 1.5 * iqr
mild_lb <- sm["1st Qu."] - 1.5 * iqr
length(which(df$MonthlyCharges > mild_ub | df$MonthlyCharges < mild_lb))</pre>
```

```
## [1] 0
```

```
# Severe Outliers
severe_ub <- sm["3rd Qu."] + 3 * iqr
severe_lb <- sm["1st Qu."] - 3 * iqr
length(which(df$MonthlyCharges > severe_ub | df$MonthlyCharges < severe_lb))</pre>
```

## [1] 0

There are no mild nor severe outliers in MonthlyCharges.

#### TotalCharges

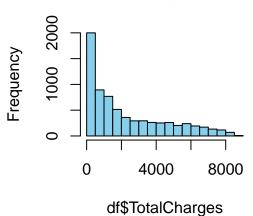

It is a numerical variable. It does contain 11 NA values.

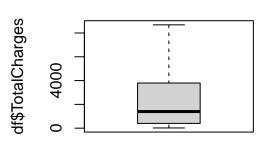

```
## Min. 1st Qu. Median Mean 3rd Qu. Max. NA's
## 18.8 401.4 1397.5 2283.3 3794.7 8684.8 11
```

## [1] 11

# **Outlier analysis**

#### ui y i utal Ci i ai ges

#### ## [1] 11

Let's look for outliers.

```
sm <- summary(df$TotalCharges)
iqr <- sm["3rd Qu."] - sm["1st Qu."]
# Mild Outliers
mild_ub <- sm["3rd Qu."] + 1.5 * iqr
mild_lb <- sm["1st Qu."] - 1.5 * iqr
length(which(df$TotalCharges > mild_ub | df$TotalCharges < mild_lb))</pre>
```

#### ## [1] 0

```
# Severe Outliers
severe_ub <- sm["3rd Qu."] + 3 * iqr

length(which(df$TotalCharges > severe_ub | df$TotalCharges < severe_lb))</pre>
```

#### ## [1] 0

There are no mild nor severe outliers.

barplot(table(df\$Churn), col="skyblue")

#### 1.1.4 Target variable:

Churn It is the target variable. It is binary, describes whether the customer churned or not (Yes or No). table(df\$Churn)

```
##
## No Yes
## 5174 1869
prop.table(table(df$Churn))
##
## No Yes
## 0.7346301 0.2653699
```

**##** [1] 0

## 2 Data preprocessing

#### 2.0.1 Recode variables into correct type

We shall reconvert the type of certain variables that are encoded with wrong type. First, we convert the character variables (except the ID) into factors.

```
char_cols <- which(sapply(df, is.character))
df[, char_cols[-1]] <- lapply(df[, char_cols[-1]], as.factor)</pre>
```

Also, we convert the numerical variable SeniorCitizen into a factor.

```
df$SeniorCitizen<- factor(df$SeniorCitizen)</pre>
```

#### 2.0.2 Data imputation

```

##
```

Only the variable TotalCharges has NA's.

The missing data corresponds to the individuals that have not payed yet the charges of the current month, we can guess that are new clients of the company.

Duplicate values: no

```
length(unique(df$customerID))
## [1] 7043
These NA exist because the costumer hasn't payed yet that month (tenure is 0). We convert these NA to 0.
ll <- which(is.na(df$TotalCharges))
df[ll,"TotalCharges"] <- 0</pre>
```

#### 2.0.3 Correlation between categorical

The categorical variables MultipleLines and PhoneService are 100% correlated. We might have multicollinearity between these two variables.

```
contingency_table<-table(df$MultipleLines,df$PhoneService)
sqrt(chisq.test(contingency_table)$statistic / (sum(contingency_table) * (min(dim(contingency_table)) -
## X-squared
## 1</pre>
```

#### 2.0.4 Profiling

## tenure

## TotalCharges

#### ## MonthlyCharges 0.03738671 2.706646e-60

Regarding to the results of the test  $Chi^2$  all correlations with the variables are significant since the p-value is less than 0,05. Since the response variable is binary, we have different results for each answer and also for all outcomes of the categorical parameters.

The parameters that have a higher positive relation with the costumers that don't churn are the ones that have a negative relation when the response variable is "Yes". In the same vein, we can observe that the parameters that have a negative relation with the costumers that churn are "OnlineSecurity" and "TechSupport" when the answer is "No", the same parameters that have a positive relation when the costumers churn. We can see that the target answer "Yes" and "No" have an approximate opposite correlations with the explanatory variables.

#### 2.1 Modelling

#### 2.1.1 Data transformations:

Recall that the following variables:

- OnlineSecurity
- OnlineBackup
- DeviceProtection
- TechSupport
- StreamingTV
- StreamingMovies

are categorical variables with 3 levels: No/No internet service/Yes.

We observe that they contain "No internet service" as a response. We have a variable called *InternetService* that is a categorical variable with 3 levels: DSL/Fiber optic/No. Whenever *InternetService*="No" implies -> var="No internet service". Therefore we decided to transform the level "No internet service" into "No" in the 6 variables above since this variable will specify.

```
df$OnlineSecurity[df$OnlineSecurity=="No internet service"] <- "No"
df$OnlineBackup[df$OnlineBackup=="No internet service"] <- "No"
df$DeviceProtection[df$DeviceProtection=="No internet service"] <- "No"
df$TechSupport[df$TechSupport=="No internet service"] <- "No"
df$StreamingTV[df$StreamingTV=="No internet service"] <- "No"
df$StreamingMovies[df$StreamingMovies=="No internet service"] <- "No"</pre>
```

We saw that *MultipleLines* is 100% related with *PhoneService*. The reason is similar as the previous parameters: one answer of *MultipleLines* is "No phone service". We set this answer to "No" since we don't lose the information because it is contained inside the parameter *PhoneService*.

```
df$MultipleLines[df$MultipleLines=="No phone service"] <- "No"
```

#### 2.1.2 Modelling:

```
set.seed(1234)
m <- floor(0.7*nrow(df))
train_d <- sample(seq_len(nrow(df)), size = m)

train <- df[train_d,]
test <- df[-train_d,]</pre>
```

Recall that the target variable is *Churn*.

#### 2.1.3 Numerical Variables

#### Null Model

```
We start the modelling by the null model.
```

```
mod0 <- glm(Churn ~ 1, data=train, family=binomial)</pre>
mod0$deviance
## [1] 5694.218
We continue by adding the numerical variables and assessing the model.
which(sapply(df, is.numeric))
##
           tenure MonthlyCharges
                                    TotalCharges
##
                6
                                              20
                              19
Tenure
mod1 <- glm(Churn ~ tenure, data=train, family=binomial)</pre>
mod1$deviance;AIC(mod0,mod1) #summary(mod1)

                  4467.5
## 1
         4927
## 2
         4926
                  4460.6 1
                              6.8951 0.008643 **
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
AIC(mod3) #4468.55
## [1] 4468.555
vif(mod3)
##
          tenure MonthlyCharges
                                  TotalCharges
##
       14.730657
                       2.271293
                                     18.869079
```

It is significant enough but we can also see that *TotalCharges* has a high VIF, so it has high multicollinearity. We decide to not include it in the model.

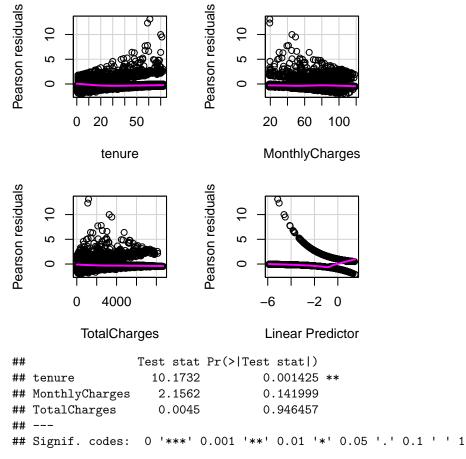

#### 2.1.4 Inlfuential data

```
inf1 <- influence.measures(mod3)
sum(residuals(mod3,'deviance')^2)
## [1] 4460.555
sum(residuals(mod3,'pearson')^2)
## [1] 5196.056
influential_indices <- which(infl$is.inf == TRUE)
length(influential_indices)
## [1] 209
length(train$customerID)
## [1] 4930</pre>
```

#### 2.1.5 Residuals

We have 209 influential points out of 4930.

```
par(mfrow = c(2, 2))
residualPlots(mod3)
```

The residuals need to be nearer to the 0 and they have homocedasticity.

#### 2.1.6 Categorical Variables

##

Now, we shall add the categorical variables. The order of addition is significant, therefore we start by adding the most correlated variables with the target.

```
**Contract*
mod4 <- glm(Churn ~ tenure + MonthlyCharges + Contract, data=train, family=binomial)</pre>
AIC(mod4) #4302.2 better
## [1] 4302.234
anova( mod3, mod4, test="Chisq") #significant
## Analysis of Deviance Table
##

```

We don't include the parameter because it does not improve the model.

#### 2.1.7 Inlfuential data

We check the influential data after including all categorical variables .

```
infl_2 <- influence.measures(mod17)
sum(residuals(mod17,'deviance')^2)

## [1] 4103.434
sum(residuals(mod17,'pearson')^2)

## [1] 4919.679
influential_indices_2 <- which(infl_2$is.inf == TRUE)
length(influential_indices_2)

## [1] 98
length(train$customerID)</pre>
```

## [1] 4930

##

The influential data has reduced until 98 tuples.

#### 2.1.8 Interactions

We need to search for interactions. Possible interactions:

#### 2.1.8.1 Dependents and Multiple Lines

```

Having both interactions improves the model but VIF gets worse. The best model is with SeniorCitizen and PaymentMethod interaction (mod21)

```

                               1.385364 1
                                                   1.177015
## SeniorCitizen
                               6.404190 1
                                                   2.530650
## PaymentMethod
                               2.532835 3
                                                   1.167529
## SeniorCitizen:PaymentMethod 10.154436 3
                                                   1.471553
```

We keep this last model because we have the best AIC with the best VIF.

#### 2.1.9 Inlfuential data

We check the influential data after including the interactions and the second order variable.

```
infl_3 <- influence.measures(mod23.4)
sum(residuals(mod23.4,'deviance')^2)

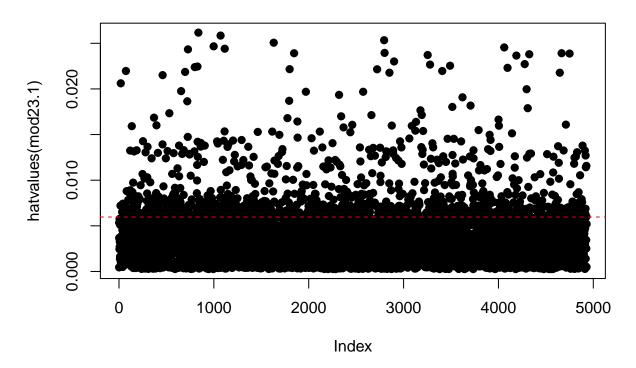

## [1] 4017.531
sum(residuals(mod23.4,'pearson')^2)

## [1] 4952.141
influential_indices_3 <- which(infl_3$is.inf == TRUE)
length(influential_indices_3)

## [1] 399
length(train$customerID)

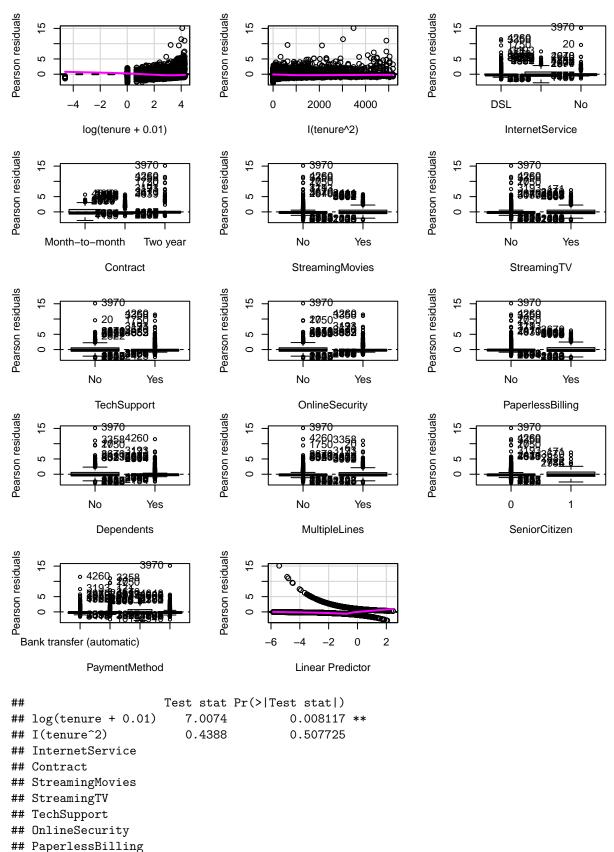

## [1] 4930
#Leverage values
plot(hatvalues(mod23.1), pch = 19, main = "Leverage Plot")</pre>
```

# **Leverage Plot**

We have more influential data than before, 399 tuples. We see that they are distributed randomly. We consider to not delete this data because it gives us important information for the model.

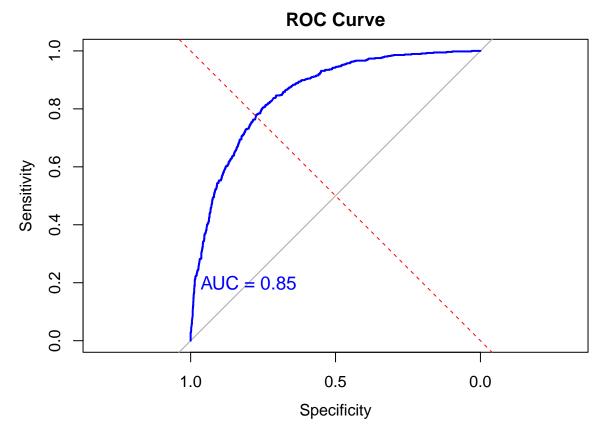

#### 2.1.10 Residuals

```
## Dependents
## MultipleLines
## SeniorCitizen
## PaymentMethod
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

We see that we have improved the residuals of the model. We can observe that we have homoscedasticity because they are randomly distributed considering that the model is binary.

```
2.1.11 Predictions
#selecting the parameters that we have in the model
#test_data <- test[c(3,5,6,8,9,10,13,14,15,16,17,18)]
pred_prob <- predict(mod23.4, newdata = test, type="response")</pre>
churn_pred<- ifelse(pred_prob>0.5, "Yes", "No")
table(churn_pred)
## churn_pred
##
    No Yes

        Yes
## 1547
        566
#Confusion table
tt <- table(churn_pred, test$Churn);tt</pre>
##
##
  churn_pred
                    Yes
##
          No 1409
                    268
          Yes 138 298
100*sum(diag(tt))/sum(tt) #80.79
## [1] 80.78561
The accuracy of our model is good, it is 80.79.
roc_curve <- roc(test$Churn, pred_prob)</pre>
## Setting levels: control = No, case = Yes
## Setting direction: controls < cases
# Plot the ROC curve
plot(roc_curve, main = "ROC Curve", col = "blue", lwd = 2)
# Add diagonal reference line for comparison
abline(a = 0, b = 1, lty = 2, col = "red")
# Add AUC (Area Under the Curve) value to the plot
text(0.8, 0.2, paste("AUC =", round(auc(roc_curve), 2)), col = "blue", cex = 1.2)
```

Our Area Under the Curve for ROC curve is 0.85 so it is high. #Interpretation

## 2.2 Final Model

Our final model is:

```
Y = -0.58 - 0.5 \cdot log(\text{tenure} + 0.01) + 0.00005 \cdot \text{tenure}^2 \\ + 0.54 \cdot \text{InternetServiceFiber optic} - 0.97 \cdot \text{InternetServiceNo} \\ - 0.75 \cdot \text{ContractOne year} - 1.90 \cdot \text{ContractTwo year} \\ + 0.26 \cdot \text{StreamingMoviesYes} + 0.33 \cdot \text{StreamingTVYes} \\ - 0.22 \cdot \text{TechSupportYes} - 0.28 \cdot \text{Online SecurityYes} \\ + 0.33 \cdot \text{PaperlessBillingYes} - 0.23 \cdot \text{DependentsYes} \\ + 0.32 \cdot \text{MultipleLinesYes} - 0.15 \cdot \text{SeniorCitizen1} \\ - 0.25 \cdot \text{PaymentMethodCredit card} + 0.27 \cdot \text{PaymentMethodElectronic check} \\ + 0.87 \cdot \text{SeniorCitizen1:PaymentMethodCredit card} \\ + 0.28 \cdot \text{SeniorCitizen1:PaymentMethodElectronic check} \\ + 1.10 \cdot \text{SeniorCitizen1:PaymentMethodMailed check}
```

We can observe in our final model that there are parameters with a negative with the target variable. These variables are categorical, this means that when this event happens, it is less probable that the costumer churns. In this case, we see that if they have a contract of one year it is less probable that they churn, but

even more less probable when the contract is for two years. We can also interpret that if the costumer has internet service it also reduces the probabilities for the costumer to leave the company.

On the other hand, we can see parameters that have a positive relation with the target variable. This implies that when the event for the categorical variable happens, it is more probable that the costumer will churn. For example, if the costumer is a senior citizen and the payment method is mailed check it is more probable that the costumer will leave the company. We can also see that if the costumer has multiple lines it also increases the probabilities for the costumer to churn.

# 3 Annex

#### 3.2 Balanced data

If we calculate other metrics, we can see that our model has not a very good precision, recall or f1 score.

```
true_positives <- tt[2, 2]</pre>
false_positives <- tt[1, 2]</pre>
false_negatives <- tt[2, 1]</pre>
precision <- true_positives / (true_positives + false_positives)</pre>
precision
## [1] 0.5265018
recall <- true_positives / (true_positives + false_negatives)</pre>
recall
## [1] 0.6834862
# F1 Score
f1_score <- 2 * (precision * recall) / (precision + recall)</pre>
```

```
## [1] 0.5948104
```

f1\_score

##

We could try to balance the target variable and see if there is any improvement. To do that we will not do a mechanic stepwise, we will use an authomatic step.

```

Balancing the target variable helps us improve the precision metric. The others not that much.
